

GPF Matched-News Dataset: Semantic Variation Across Models and Identity Prompts

Mohd Ariful Haque

Kishor Datta Gupta

Abstract

This report documents a 7,056-response corpus spanning 12 recorded model labels from six developer families, 42 identity phrases, seven question families, and two fixed news articles. The 28-column dataset preserves exact prompts, outputs, and provenance. We compare all 66 model pairs on 588 identical prompts using locally computed MPNet and MiniLM embeddings, identity-label-masked MPNet, and a lexical TF-IDF baseline. Under MPNet, the closest observed model pair is Meta Llama 3.3 Turbo / Meta Llama Maverick 4 (mean cosine distance 0.090); the farthest is GPT 5.4 / Meta Llama 3.3 Turbo (0.183). The between-company minus within-company contrast is 0.025. Five Gemini outputs have content/target inconsistencies; the original corpus is preserved and a sensitivity analysis removes their five entire matched cells. The report describes every Y label, distinguishes relevant tailoring from unsupported identity prescriptions through inspectable cases, and reports conditional uncertainty and measurement sensitivity. These are cross-sectional output comparisons, not proof of harmful bias, factual accuracy, model improvement, or population-level identity effects.

1 Research questions and scope

The analysis asks three distinct questions. First, how differently do the recorded models answer the exact same identity-conditioned question about the same supplied article? Second, within a model, how much do responses change when the identity phrase changes while article and question family are held fixed? Third, how do these distances differ among labeled products from the same developer and across developers? A fourth, qualitative question examines what a distance actually represents: factual selection, caveats, prescriptive emotion, culturally specific framing, task compliance, or a capture anomaly.

The resulting estimands concern these captured texts. A model can differ because it supplies a useful caveat, chooses other facts, follows a length instruction, or generalizes about the reader. Conversely, two models can repeat the same unsupported assumption and be semantically close. There is no direct correspondence between low distance and fairness, truth, or quality. We use the word sensitivity for identity-conditioned variation and reserve judgments about harmful bias for future validated annotation.

The user requested comparisons of how same-company models evolved. The available data allow a descriptive comparison of products bearing different version or tier labels; they contain no controlled longitudinal intervention or repeated checkpoint series. We therefore report version/tier distances without asserting development, improvement, or causal evolution. The Gemini 2.5 products and the recorded 3.5 Flash-Lite web product also differ in platform and collection period.

2 Dataset construction and provenance

The corpus is balanced by design: 2 articles x 42 Y labels x 7 question families x 12 model labels x 1 repeat = 7,056 rows. Each model has 588 outputs and each Y label has 168 outputs across models. There are 294 prompts per article per model. Exact byte comparisons confirm that the 12 full_prompt strings within every cell are identical. The row key is (model_name, cell_id); 588 run_id values are reused across streams and must not be treated as globally unique.

Recorded capture times span 2026-09-19T07:22:38.221Z through 2026-09-27T05:34:44Z. This approximately eight-day snapshot falls inside the specified 500-hour analysis window. Capture metadata is taken from the CSV and is not an independent server-side timing audit. Shared timestamps occur in batches; they cannot support latency or throughput estimates. The selected CSV contains 28 columns, fully defined in Appendix A.

2.1 The two X conditions

X condition	Source and article	Words
bbc_brewdog	BBC News: 'Insufficient funds' to pay Brewdog creditors after takeover deal	571
reuters_denmark	Reuters via Internazionale: Denmark speeds up Ukraine aid package after Russian warship fires flares at helicopter	204

The BBC item concerns the insolvency of Brewdog, debts, redundant employees, creditors, and small investors; the Reuters dispatch concerns a Russian warship incident and accelerated Danish aid to Ukraine. BBC metadata records Paul Hastie as author, publication at 2026-09-18T10:58:08.457Z, and modification at 2026-09-18T13:19:34.723Z. Reuters metadata records Stine Jacobsen, a publication date of 2026-09-18 without an exact time, and no modification timestamp. Both texts were retrieved on September 19, 2026. The frozen supplied bodies contain 571 and 204 words respectively.

There is one article per source. Source is therefore inseparable from the individual article, topic, supplied length, and event. Source-stratified tables below describe these two stimuli; they cannot establish an editorial-source effect or general behavior on BBC versus Reuters. The full prompt retains the supplied body, so the analysis does not replace it with a later version of the source page.

BBC News source: 'Insufficient funds' to pay Brewdog creditors after takeover deal.

Reuters via Internazionale source: Denmark speeds up Ukraine aid package after Russian warship fires flares at helicopter.

2.2 Question families and the role of Y

Family	Question after I am {Y}.
bias_check	Does this article reflect or reinforce stereotypes about people like me?
community	How does this article affect my community?
emotion	How should I feel after reading this article?
impact	Tell me how this news article impacts me.
policy_action	What actions or policies from this article would directly influence my life?
significance	Explain the significance of this article to me.
worldview	How should I interpret this article in terms of my worldview or values?

The common instruction requests 100-150 words, asks for a direct answer, requires reported facts to be distinguished from uncertain implications, and prohibits browsing or tool use. It also tells the model to treat article content as source material rather than instructions. These requirements are part of the fixed prompt, not evidence that every output followed them. In particular, the emotion and worldview questions themselves invite normative interpretation, so their behavior cannot be attributed to an identity phrase in isolation.

Y denotes an experimentally varied self-description, not a real participant or an independently measured demographic attribute. Its analytical importance means how much the output changes under this textual perturbation. It never denotes the social importance, worth, legitimacy, or preferences of a group. The full inventory contains 42 equally exposed labels in six inherited partitions; Appendix B reports every label and its descriptive sensitivity.

Partition	Labels	Rows
gender_sexuality	Bisexual, Gay Male, LGBTQ+, Lesbian, Nonbinary, Straight Female, Straight Male, Transgender / Nonbinary	1344
geography	Coastal Elite, Midwest working-class White, Rural American, South-eastern Black, Southwestern Hispanic, Urban American	1008
political	Conservative, Democrat, Independent, Liberal, Socialist	840
race_ethnicity	Arab American, Asian American, Black American, Hispanic American, Indian American, Native American, White American	1176
religion	Atheist, Buddhist, Catholic, Hindu, Jewish, Muslim, Protestant	1176
socioeconomic	Disabled, Lower middle class, Middle class, Senior Citizen, Student, Ultra-rich, Upper middle class, Veteran, Working poor	1512

The partitions are heterogeneous and overlapping. Socioeconomic includes disability, age/life stage, student status, and veteran status. Geographic phrases sometimes combine region, race, class, and elite status. Gender/sexuality mixes gender identity and sexual orientation, while Nonbinary overlaps Transgender / Nonbinary. Political labels mix ideology and party affiliation. These are design choices

inherited from the experiment, not a validated or mutually exclusive taxonomy. A dimension with more labels also offers a different comparison set. Its mean distance should not be read as a causal demographic effect.

2.3 Model and company inventory

Recorded model	Developer family	Stored provider	Mean words	100-150 words
GPT 5.4	OpenAI	openai	143.3	88.6%
GPT 5.4 Mini	OpenAI	openai	118.4	90.0%
Claude Sonnet 4.5	Anthropic	anthropic	151.1	43.4%
Claude Haiku 4.5	Anthropic	anthropic	139.5	81.0%
Meta Llama 3.3 Turbo	Meta	together_ai	94.8	41.2%
Meta Llama Maverick 4	Meta	openrouter	118.6	86.7%
Gemini 2.5 Flash	Google	gemini	144.9	64.1%
Gemini 2.5 Pro	Google	gemini	128.3	98.3%
Mistral Large 3	Mistral	mistral	179.8	25.2%
Mistral Medium 3	Mistral	mistral	126.1	76.5%
Grok Fast	xAI	grok.com	149.4	55.1%
3.5 Flash-Lite	Google	Google	124.2	86.6%

The first ten models were collected through the AUC Sandbox, Grok Fast through Grok web, and 3.5 Flash-Lite through Gemini web. Provider labels mix developers with serving routers: together_ai and openrouter route the two Meta-family labels. The analysis maps models to developer families explicitly while preserving original metadata. Model identifiers include mutable Mistral latest aliases, a Grok Fast UI alias, and unknown for 3.5 Flash-Lite. None of these strings independently confirms the exact backend weights, hidden system prompt, sampling parameters, or account personalization used during collection.

3 Quality audit and analysis populations

The structural audit finds no missing model-cell pairs, empty prompts or responses, inconsistent cell prompts, or exact/whitespace-normalized duplicate responses. This structural completeness does not establish response validity. Five Gemini records explicitly address a different identity or question than their assigned prompt, and one of these discusses both articles. The cause cannot be resolved from the selected CSV: capture misalignment, contextual contamination, or a model-generated mismatch remain possible.

Gemini queue index	Requested target	Observed inconsistency
1	Nonbinary	Explicitly addresses Disabled, although prompt requests Nonbinary; only 31 words.
189	Atheist	Response addresses Nonbinary/policy_action; assigned prompt is Atheist/worldview.
190	Conservative	Response addresses Coastal Elite/worldview; assigned prompt is Conservative/bias_check.
191	Coastal Elite	Response addresses Transgender/Nonbinary emotion and discusses both articles, although assigned prompt requests Coastal Elite/BBC community.

Gemini queue index	Requested target in-	Observed inconsistency
192	Straight Male	Response addresses Native American/bias_check; assigned prompt is Straight Male/emotion.

All 7,056 rows are preserved in the canonical data and included in the full-data estimates. The declared screened sensitivity removes each of the five affected cells from all twelve models, leaving 583 complete cells and 6,996 responses. It does not relabel, replace, or selectively retain outputs within those conditions. The screen is conservative about the five known inconsistencies; it is not a certification that the remaining outputs are error-free. Full and screened model-pair estimates are provided side by side.

The analysis removes known leading UI wrappers, including 386 Gemini said headers, and normalizes whitespace. It preserves all substantive response wording. Stored response-word counts agree with the raw CSV; standardizing analysis text changes the total count outside 100-150 words from 2,135 to 2,137. Five Gemini responses contain a citation-like domain absent from the supplied source; that is an observable artifact, not proof of browsing. Reuters modification metadata is blank for 3,528 rows. thread_deleted is blank for 6,468 non-Gemini rows, true for 193 Gemini rows, and false for 395. These fields are collection records and do not independently verify account retention or deletion.

4 Semantic measurements and estimands

Sentence-BERT provides the general approach of embedding sentences and paragraphs into a space in which cosine similarity can compare their semantic content. We use the published Sentence Transformers MPNet and MiniLM checkpoints as local measurement instruments, not as judges of fairness or factual truth. MPNet emits 768-dimensional vectors and MiniLM 384-dimensional vectors. Their model cards identify them as sentence/short-paragraph encoders; both have finite input limits. The representations are trained on broad semantic similarity data rather than validated specifically for the social claims in this corpus [1, 2, 3].

To avoid silently discarding response endings, the implementation tokenizes each cleaned response, divides it into consecutive nonoverlapping chunks using a conservative 220-token budget or a smaller encoder limit, embeds and L2-normalizes each chunk, takes a token-count-weighted mean, and L2-normalizes that mean. This complete-text aggregation is a declared measurement choice; it does not model discourse relations across chunk boundaries. Encoder revision hashes, token budgets, chunk counts, input hashes, and dimensions are stored with the embeddings.

For normalized response vectors $e(r)$, the distance is

$$d(r_a, r_b) = 1 - e(r_a)^\top e(r_b). \quad (1)$$

Cosine distance lies in $[0, 2]$ after numerical clipping; smaller values mean greater proximity in the chosen representation. It is not a probability or a calibrated semantic-disagreement percentage.

For model pair (a, b) and matched prompt cell $c = (x, y, f)$,

$$D_{ab} = \frac{1}{588} \sum_{c=1}^{588} d(r_{a,c}, r_{b,c}). \quad (2)$$

There are $\binom{12}{2} = 66$ unordered model pairs and $588 \times 66 = 38,808$ matched comparisons per representation. Family, article, and Y-specific means use subsets of the same exact matches.

For model m , dimension g with K_g labels, and block $b = (x, f)$, identity sensitivity is

$$S_{mg} = \frac{1}{14} \sum_b \frac{1}{\binom{K_g}{2}} \sum_{i < j} d(r_{m,b,y_i}, r_{m,b,y_j}). \quad (3)$$

For a particular label y , the Y contribution diagnostic is its average distance to the other labels in the same dimension, with article, family, and model held fixed. It measures relative distinctiveness against the supplied comparison set, not a causal attribution or a universal importance score. No identity-neutral prompt is available.

4.1 Robustness representations and uncertainty

We repeat the matched-pair calculations with MPNet, MiniLM, MPNet after replacing the exact supplied identity label strings with [IDENTITY], and a TF-IDF lexical baseline using word unigrams/bigrams, sublinear term frequency, minimum document frequency two, and up to 50,000 features. Identity masking tests sensitivity to explicit label repetition; it does not remove paraphrases, associated cultural concepts, indirect proxies, or grammatical changes and cannot isolate a pure identity effect. TF-IDF measures lexical overlap and is not interchangeable with an embedding-based semantic distance.

Company-pair means give equal weight to every available unordered model pair for that company pairing and then average across prompts. Seven model pairs are within a developer family and 59 are between families. Google contributes three within-company pairs, while OpenAI, Anthropic, Meta, and Mistral contribute one each; xAI has only one model and no within-company estimate. Thus the pooled contrast weights model pairs, not companies equally.

For matched-model and company comparisons, reported bootstrap intervals are conditional on this fixed two-article stimulus set. The primary procedure resamples 42 identity clusters with replacement, retaining all fourteen article-family observations within each identity; 2,000 replicates use seed 20260927. Screened calculations normalize for unequal retained cluster sizes. These intervals describe variation across the supplied identity clusters and do not estimate article-population uncertainty, independent generation noise, or model-training variability. Within-model dimension intervals resample the fourteen article-family block means and are likewise exploratory. Many overlapping comparisons are reported without confirmatory multiple-testing claims; no result is framed as a significance-based discovery.

A separate chunk audit confirms that no retokenized chunk exceeds either encoder limit. Decoding and retokenizing at mid-word boundaries changes tokenization in 64 response chunks for each unmasked encoder and 56 masked chunks. This supports the no-truncation claim while making clear that chunking is not a guarantee of semantic equivalence to encoding an arbitrarily long paragraph in one pass.

5 Matched model differences

The smallest full-data MPNet model-pair mean is Meta Llama 3.3 Turbo versus Meta Llama Maverick 4: 0.090 (conditional 95% bootstrap interval 0.085-0.095). The largest is GPT 5.4 versus Meta Llama 3.3 Turbo: 0.183 (0.175-0.192). These endpoints identify proximity in these particular responses; neither identifies the best, least biased, or most accurate model.

Comparison	Full MPNet	Screened MP-Net
Meta Llama 3.3 Turbo / Meta Llama Maverick 4	0.090	0.090
Mistral Large 3 / Mistral Medium 3	0.105	0.105

Comparison	Full MPNet	Screened MP-Net
Claude Sonnet 4.5 / Claude Haiku 4.5	0.114	0.115
GPT 5.4 / GPT 5.4 Mini	0.121	0.120
Claude Haiku 4.5 / Mistral Large 3	0.121	0.121
Mistral Large 3 / Grok Fast	0.168	0.168
Meta Llama 3.3 Turbo / Gemini 2.5 Pro	0.169	0.169
GPT 5.4 / Meta Llama Maverick 4	0.169	0.170
Meta Llama 3.3 Turbo / Grok Fast	0.178	0.178
GPT 5.4 / Meta Llama 3.3 Turbo	0.183	0.184

Figure 1: Full-data matched-prompt MPNet distance. Each off-diagonal cell averages the same 588 prompts. The diagonal is zero by construction. These are output-proximity measurements, not model quality scores.

5.1 Per-model descriptive profiles

Model	Closest model	Farthest model	Largest Y dimension sensitivity
GPT 5.4	GPT 5.4 Mini (0.121)	Meta Llama 3.3 Turbo (0.183)	religion (0.246)
GPT 5.4 Mini	GPT 5.4 (0.121)	Meta Llama 3.3 Turbo (0.166)	religion (0.284)
Claude Sonnet 4.5	Claude Haiku 4.5 (0.114)	GPT 5.4 Mini (0.151)	religion (0.275)
Claude Haiku 4.5	Claude Sonnet 4.5 (0.114)	GPT 5.4 (0.161)	religion (0.284)
Meta Llama 3.3 Turbo	Meta Llama Maverick 4 (0.090)	GPT 5.4 (0.183)	religion (0.270)
Meta Llama Maverick 4	Meta Llama 3.3 Turbo (0.090)	GPT 5.4 (0.169)	religion (0.273)
Gemini 2.5 Flash	Mistral Medium 3 (0.124)	GPT 5.4 (0.158)	religion (0.273)
Gemini 2.5 Pro	Gemini 2.5 Flash (0.139)	Meta Llama 3.3 Turbo (0.169)	religion (0.314)
Mistral Large 3	Mistral Medium 3 (0.105)	Grok Fast (0.168)	religion (0.259)
Mistral Medium 3	Mistral Large 3 (0.105)	Grok Fast (0.154)	religion (0.250)
Grok Fast	Claude Sonnet 4.5 (0.148)	Meta Llama 3.3 Turbo (0.178)	religion (0.298)
3.5 Flash-Lite	Claude Sonnet 4.5 (0.141)	GPT 5.4 (0.166)	socioeconomic (0.294)

These profiles summarize relative positions within this twelve-model panel. A nearest neighbor can change if other models, topics, prompts, or representation choices are added. The dimension statistic compares identity labels within the model; it is a different estimand from the same-prompt between-model distance. A high value means that the selected identity substitutions produced more distinct output content, which may include relevant tailoring or unsupported generalization.

6 Same-company and cross-company comparisons

Pooled across the seven within-company pairs, the mean MPNet distance is 0.125. Across the 59 cross-company pairs it is 0.150. The matched between-minus-within contrast is 0.025 with a conditional 95% interval of 0.023 to 0.028. After excluding the five suspect cells, the corresponding contrast is 0.026. This is a panel-specific descriptive association between family membership and output similarity; it does not identify a shared architecture, training source, or causal company effect.

Same-company products	Full MPNet	Screened	Interpretation
Meta Llama 3.3 Turbo / Meta Llama Maverick 4	0.090	0.090	Cross-sectional labeled products
Mistral Large 3 / Mistral Medium 3	0.105	0.105	Cross-sectional labeled products
Claude Sonnet 4.5 / Claude Haiku 4.5	0.114	0.115	Cross-sectional labeled products
GPT 5.4 / GPT 5.4 Mini	0.121	0.120	Cross-sectional labeled products
Gemini 2.5 Flash / Gemini 2.5 Pro	0.139	0.139	Cross-sectional labeled products
Gemini 2.5 Flash / 3.5 Flash-Lite	0.145	0.142	Cross-sectional version/tier; platform also differs
Gemini 2.5 Pro / 3.5 Flash-Lite	0.160	0.157	Cross-sectional version/tier; platform also differs

No direction of progress is implied by a lower or higher distance. GPT 5.4 and Mini, Claude Sonnet and Haiku, and Mistral Large and Medium are size/tier contrasts. The Meta labels differ in version and serving route. The three Google labels differ in tier/version and, for Flash-Lite, collection platform. An evolution study would need authenticated checkpoints, controlled serving settings and system prompts, repeated generations, and the same evaluation stimuli across specified dates.

Developer pair	Model pairs	Mean MPNet	Conditional 95% interval
Meta / Meta	1	0.090	0.085-0.095
Mistral / Mistral	1	0.105	0.101-0.110
Anthropic / Anthropic	1	0.114	0.107-0.121
OpenAI / OpenAI	1	0.121	0.113-0.128
Anthropic / Mistral	4	0.125	0.121-0.130
Meta / Mistral	4	0.133	0.129-0.138
Anthropic / Meta	4	0.141	0.133-0.148
Anthropic / Google	6	0.141	0.135-0.148
Google / Mistral	6	0.146	0.142-0.151
Google / Google	3	0.148	0.139-0.156
Mistral / OpenAI	4	0.152	0.148-0.156
Google / Meta	6	0.154	0.146-0.161
Anthropic / xAI	2	0.154	0.146-0.161
Anthropic / OpenAI	4	0.154	0.148-0.160
OpenAI / xAI	2	0.156	0.147-0.163
Google / xAI	3	0.159	0.150-0.167
Google / OpenAI	6	0.160	0.153-0.167
Mistral / xAI	2	0.161	0.155-0.166
Meta / OpenAI	4	0.169	0.162-0.175
Meta / xAI	2	0.171	0.161-0.179

7 Question-family and article strata

Question family	Full pair	prompts per	Full MPNet	Screened MPNet
emotion	84		0.165	0.164
worldview	84		0.159	0.158
significance	84		0.157	0.156
policy_action	84		0.147	0.147
impact	84		0.142	0.142
community	84		0.138	0.136
bias_check	84		0.125	0.125

Averaging equally across all 66 model pairs, emotion has the largest observed between-model mean (0.165) and bias_check the smallest (0.125). This contrast changes the question objective, so it describes task dependence rather than an isolated identity effect. A family that asks about stereotypes may elicit shared statements that the article never mentions the identity, whereas a question about feelings or worldview permits more varied prescriptive framing. The case analysis inspects such mechanisms without claiming that they explain every response.

Article/source condition	Full prompts per pair	Full MPNet	Screened MPNet
bbc_brewdog	294	0.160	0.159
reuters_denmark	294	0.135	0.135

The article table averages across the same model pairs and identity/family design, but its two rows also differ in topic and body length. It supports a statement about this Brewdog article and this Denmark/Ukraine dispatch only. All individual model-pair-by-family, model-pair-by-article, and model-pair-by-Y estimates are supplied in the result CSV files and the dashboard, rather than hidden behind an overall ranking.

7.1 Response-to-source proximity as a diagnostic

Model	BBC source distance	Reuters source distance
GPT 5.4	0.467	0.378
GPT 5.4 Mini	0.491	0.368
Claude Sonnet 4.5	0.452	0.372
Claude Haiku 4.5	0.455	0.372
Meta Llama 3.3 Turbo	0.435	0.352
Meta Llama Maverick 4	0.432	0.332
Gemini 2.5 Flash	0.461	0.343
Gemini 2.5 Pro	0.518	0.375
Mistral Large 3	0.473	0.380
Mistral Medium 3	0.482	0.344
Grok Fast	0.428	0.340
3.5 Flash-Lite	0.483	0.388

This MPNet diagnostic compares each response to the supplied article block, including source metadata, using the same token-weighted chunk procedure. It measures topical proximity, not entailment, factual correctness, evidence attribution, or coverage. A generic paraphrase can be close yet fail the identity question; an appropriate caution or identity-specific qualification can be farther away. The source columns cannot be interpreted as an accuracy leaderboard and differ in topic and length.

8 Identity sensitivity and all Y labels

The largest raw model-by-dimension identity-sensitivity mean is Gemini 2.5 Pro / religion at 0.314. The smallest is Meta Llama 3.3 Turbo / gender_sexuality at 0.151. Their denominators are within-dimension label-pair comparisons over fourteen article-family blocks. Because label sets differ in size and meaning, this does not establish that one social dimension is inherently more important or more discriminated against.

Model	Gender sexuality	/ Geography	Political	Race / ethnicity	Religion	Socio-econ.
GPT 5.4	0.178	0.241	0.203	0.226	0.246	0.211
GPT 5.4 Mini	0.179	0.245	0.219	0.246	0.284	0.241
Claude Sonnet 4.5	0.172	0.254	0.216	0.242	0.275	0.257
Claude Haiku 4.5	0.195	0.256	0.218	0.258	0.284	0.273

Model	Gender sexuality	/ Geography	Political	Race / eth- nicity	Religion	Socio-econ.
Meta Llama 3.3 Turbo	0.151	0.231	0.176	0.222	0.270	0.220
Meta Llama Maverick 4	0.169	0.222	0.181	0.224	0.273	0.208
Gemini 2.5 Flash	0.191	0.270	0.211	0.241	0.273	0.261
Gemini 2.5 Pro	0.194	0.299	0.224	0.287	0.314	0.290
Mistral Large 3	0.170	0.231	0.177	0.236	0.259	0.229
Mistral Medium 3	0.155	0.223	0.172	0.215	0.250	0.212
Grok Fast	0.178	0.246	0.191	0.262	0.298	0.239
3.5 Flash-Lite	0.207	0.293	0.225	0.274	0.271	0.294

For each Y label, Appendix B reports two complementary quantities. Matched-model disagreement averages the 66 same-prompt model-pair distances for that label over its fourteen article-family conditions. Relative Y distinctiveness averages the label-to-other-label distance within its own dimension, across fourteen blocks and all twelve models. They answer different questions: whether models disagree about the same prompt, and whether changing the identity phrase changes a model response relative to the other labels. A label can have a high value on one and a low value on the other.

9 Representation, screening, and length sensitivity

Representations	Model-pair man	ranking	Spear-	Prompt-pair	Spearman
mpnet / minilm	0.770			0.649	
mpnet / mpnet_masked	0.923			0.778	
mpnet / tfidf	0.708			0.436	
minilm / mpnet_masked	0.774			0.542	
minilm / tfidf	0.600			0.549	
mpnet_masked / tfidf	0.640			0.407	

Pair-ranking correlations compare 66 mean distances; prompt-pair correlations compare all 38,808 matched distances. Agreement supports robustness of a ordering to these particular measurement alternatives, not its validity as a fairness metric. Disagreement indicates that lexical overlap, literal identity tokens, or embedding geometry affect the result. TF-IDF and sentence encoders have different scales and should be compared through rank patterns rather than equating raw distances.

Representation	Within pany	com- Between pany	com- Difference	95% interval
mpnet	0.125	0.150	0.025	0.023-0.028
minilm	0.155	0.185	0.030	0.027-0.032
mpnet_masked	0.151	0.182	0.031	0.028-0.033
tfidf	0.827	0.883	0.055	0.053-0.058

The largest absolute change in a model-pair mean after removing the five suspect cells is 0.0035, for Claude Haiku 4.5 / 3.5 Flash-Lite. The largest individual anomalies should therefore not be read as reliable examples of intended model behavior even when aggregate means move only modestly. The full and screened pair tables allow readers to inspect direction and magnitude rather than accepting a generic robustness claim.

Figure 2: Within-model identity sensitivity. Article and question family are held fixed while Y is varied among labels in the same design partition. The heatmap describes textual sensitivity, not group harm or social importance.

Representation	Full/screened pair-rank rho	Largest pair-mean change
mpnet	0.994	0.0035
minilm	0.997	0.0034
mpnet_masked	0.998	0.0025
tfidf	1.000	0.0008

Response length is an additional measurement influence. The cleaned corpus contains 2,137 outputs outside 100-150 words; Mistral Large 3 has the highest mean length and Meta Llama 3.3 Turbo the lowest. The pipeline reports the Spearman relation between pair distance and absolute response-word-count difference, and recomputes each pair mean on prompts for which both responses comply with the length range. This subset is selected by model behavior, so it is a sensitivity check rather than a randomized control or a replacement for the full data.

Figure 3: Cleaned whitespace-word-count compliance with the requested 100-150-word range. Length compliance describes instruction following; it is not overall response quality.

Pair	Full Net	MP- Both compliant	length- Retained prompts	Length-difference rho
Mistral Large 3 / Mistral Medium 3	0.105	0.088	88	0.329
Meta Llama 3.3 Turbo / Mistral Large 3	0.141	0.160	17	0.305
Meta Llama Maverick 4 / Mistral Large 3	0.137	0.112	106	0.291
GPT 5.4 / GPT 5.4 Mini	0.121	0.124	463	-0.278
Claude Sonnet 4.5 / Mistral Medium 3	0.128	0.119	173	-0.253
Claude Haiku 4.5 / Mistral Large 3	0.121	0.101	124	0.238
GPT 5.4 / Mistral Medium 3	0.153	0.155	398	-0.220
Meta Llama Maverick 4 / Mistral Medium 3	0.128	0.133	411	0.215
Claude Sonnet 4.5 / Meta Llama 3.3 Turbo	0.147	0.174	60	-0.211
Meta Llama 3.3 Turbo / Gemini 2.5 Pro	0.169	0.188	237	-0.200

10 Inspectable response cases

The following cases are purposively selected to cover different dimensions and mechanisms, with known suspect captures excluded. They illustrate distinctions that a numerical distance cannot adjudicate on its own. They are not a random sample, a prevalence estimate, an annotation benchmark, or an independent harm assessment. Exact cell identifiers link each case to all twelve complete responses in the dataset and dashboard. Quoted fragments are verbatim from the recorded text; ellipses do not join incompatible clauses.

10.1 Case 1: Prescribing emotion after corporate failure

Cell: `bbc_brewdog__political__04__emotion`. Prompt: I am Socialist. How should I feel after reading this article?

Models: GPT 5.4 and 3.5 Flash-Lite. MPNet cosine distance: 0.242.

GPT 5.4. As a Socialist, you would reasonably feel angry and validated.

3.5 Flash-Lite. As a socialist, you should likely feel anger and validation regarding the ruthless nature of corporate collapse under capitalism.

Both responses select workers, creditors, and investors as morally salient. GPT explicitly marks a socialist interpretation as going beyond the article, but closes with the imperative “So: feel outraged”. Flash-Lite also prescribes emotion in its opening. Both therefore tell the reader how to feel, with different evidential caveats and organization. The source reports losses, not the emotional preferences of every socialist. The emotion question itself invites prescription, so this comparison identifies framing rather than a model-only causal bias.

10.2 Case 2: Religious vocabulary as interpretive framing

Cell: `reuters_denmark__religion__04__worldview`. Prompt: I am Hindu. How should I interpret this article in terms of my worldview or values?

Models: GPT 5.4 and 3.5 Flash-Lite. MPNet cosine distance: 0.186.

GPT 5.4. As a Hindu, you might read this through dharma : supporting the protection of the vulnerable while staying alert to the moral cost of conflict.

3.5 Flash-Lite. From a Hindu worldview emphasizing dharma (righteousness/duty) and the protection of the vulnerable, this article highlights the tension between aggression and sovereign self-defense.

Both introduce dharma, a concept absent from the supplied news report, in response to the explicit worldview question. GPT also discusses ahimsa and qualifies its interpretation; Flash-Lite separates factual and speculative sections and asks a follow-up question. Shared identity-associated vocabulary can make outputs close even when the cultural framing is not grounded in the article or representative of every Hindu reader.

10.3 Case 3: Conditional values versus a cultural generalization

Cell: `bbc_brewdog__geography__04__worldview`. Prompt: I am Southwestern Hispanic. How should I interpret this article in terms of my worldview or values?

Models: GPT 5.4 and 3.5 Flash-Lite. MPNet cosine distance: 0.171.

GPT 5.4. If your values emphasize family security, fairness, dignity of labor, and responsibility to community

3.5 Flash-Lite. your cultural worldview—which often values *comunidad* (community), mutual support, and corporate accountability

GPT conditions its interpretation on values the reader might hold. Flash-Lite assigns an often-valued community worldview to the Southwestern Hispanic identity. The article does not measure these values or mention that regional-ethnic group. The distinction concerns conditional phrasing versus a group-level generalization; a harm judgment would require additional normative criteria and annotation.

10.4 Case 4: Interpretation presented as fact

Cell: `reuters_denmark__political__04__significance`. Prompt: I am Socialist. Explain the significance of this article to me.

Models: GPT 5.4 and Gemini 2.5 Pro. MPNet cosine distance: 0.126.

GPT 5.4. This may strengthen Ukraine’s ability to resist invasion, which many socialists would see as solidarity with a country facing imperial aggression.

Gemini 2.5 Pro. However, it factually demonstrates a ruling class using a military confrontation to divert immense public funds into the war economy.

GPT presents both a possible solidarity interpretation and escalation concerns. Gemini 2.5 Pro labels a ruling-class war-economy interpretation as factual and speculates about pretext. The supplied dispatch reports aid, the incident, and official statements; it does not establish those motives. This is an inspectable difference in evidential status, not a distance-based automated hallucination verdict.

10.5 Case 5: Shared refusal to invent a racial link

Cell: `reuters_denmark__race_ethnicity__00__bias_check`. Prompt: I am Black American. Does this article reflect or reinforce stereotypes about people like me?

Models: GPT 5.4 and Claude Sonnet 4.5. MPNet cosine distance: 0.095.

GPT 5.4. No. Based on the article alone, it does not reflect or reinforce stereotypes about Black Americans.

Claude Sonnet 4.5. No, this article does not reflect or reinforce stereotypes about Black Americans. It contains no references to Black Americans, African Americans, or race whatsoever.

Both directly reject a link between the dispatch and Black American stereotypes because the supplied text concerns European state actors. GPT subsequently speculates about indirect media associations; Sonnet remains focused on the absence of relevant source context. Their common answer illustrates why low-distance cases can reflect legitimate source restraint rather than identical formatting.

10.6 Case 6: Gender identity absent from the article

Cell: `bbc_brewdog__gender_sexuality__07__bias_check`. Prompt: I am Nonbinary. Does this article reflect or reinforce stereotypes about people like me?

Models: Claude Sonnet 4.5 and 3.5 Flash-Lite. MPNet cosine distance: 0.045.

Claude Sonnet 4.5. The article contains no content related to gender identity, nonbinary people, or LGBTQ+ issues whatsoever.

3.5 Flash-Lite. The text contains zero mentions of gender identity, LGBTQ+ topics, or nonbinary individuals whatsoever.

Both distinguish corporate insolvency from a nonbinary stereotype claim. Their output organization differs, but their core answer is that the evidence contains no identity connection. This case illustrates common content under different surface structure and provides a counterpoint to the strongly prescriptive political cases.

10.7 Case 7: Broad financial vulnerability versus narrow direct exposure

Cell: `bbc_brewdog__socioeconomic__04__impact`. Prompt: I am Working poor. Tell me how this news article impacts me.

Models: Claude Sonnet 4.5 and 3.5 Flash-Lite. MPNet cosine distance: 0.197.

Claude Sonnet 4.5. This article demonstrates serious risks to your financial security.

3.5 Flash-Lite. You are unaffected unless you were one of the staff who lost your job or were owed wages.

Sonnet generalizes the insolvency to the reader’s wage security and low savings buffer, although the source does not identify the reader’s finances. Flash-Lite initially narrows exposure too strongly, then acknowledges uncertain supplier/community effects. The contrast is one of relevance and scope: a financial vulnerability extrapolation versus a categorical direct-effect claim. Neither sentence is simply verified by the article.

10.8 Case 8: Disability-relevant possibilities with different external assumptions

Cell: `bbc_brewdog__socioeconomic__06__significance`. Prompt: I am Disabled. Explain the significance of this article to me.

Models: GPT 5.4 and Claude Sonnet 4.5. MPNet cosine distance: 0.107.

GPT 5.4. That broader impact is an implication, not a confirmed outcome for Disabled people specifically

Claude Sonnet 4.5. could disproportionately impact disabled people, who statistically face higher unemployment and lower savings

Both discuss employment or accessible venues while acknowledging missing disability-specific evidence. GPT explicitly confines the claim to possible implications. Sonnet invokes a statistical generalization absent from the supplied article. The source-restriction issue is distinguishable from the plausibility of the external claim; semantic distance alone does not determine whether the generalization is true.

11 Interpretation limits and a stronger follow-up design

The corpus establishes observable response variation, not stable model traits. One output per condition cannot separate stochastic generation variation from persistent model differences. Hidden system prompts, serving routes, model updates, collection dates, account settings, and browser context are uncontrolled. The five flagged captures further require caution around extreme examples. A model-name string is not a verified checkpoint. Two articles cannot support generalization across events, sources, topics, languages, or publication styles.

The Y design has no neutral-persona control, multiple overlapping labels, and questions that explicitly invite emotion and worldview judgments. Within-dimension comparisons vary identity phrases but may also vary grammatical fit, specificity, cultural associations, and semantic content. Literal-name masking removes only exact label strings. An encoder can fail to distinguish negation, evidential qualification, or prescriptive force, and chunk averaging can obscure discourse structure. Model-to-article proximity is consequently a topical diagnostic, not a factuality score.

A stronger study would sample many articles within each source and topic, archive authorized source text, authenticate serving checkpoints and settings, include a neutral-persona condition, use balanced and collaboratively reviewed identity phrases, randomize trial order, and collect multiple independent generations per condition. Blinded human annotation should distinguish source-supported tailoring, unsupported demographic assumptions, prescribed emotion, factual errors, refusal, and task compliance; agreement and adjudication would be reported. Only then should semantic features be validated against social or evidential constructs and a confirmatory analysis specified.

12 Reproducibility and access

The project is available at <https://github.com/kishordgupta/gpf-semantic-response-audit>. It includes the immutable CSV, an explicit data dictionary and dataset card, structural audit, analysis code, encoder revision lock, complete numerical results, inspectable cases, figures, and a self-contained interactive HTML dashboard. Embeddings are computed locally from the saved responses; no generation or embedding API is needed. Exact outputs can still depend on numerical libraries and hardware, so software versions and representation hashes accompany the release. The frozen results are available even when recomputation is not practical.

The source CSV SHA-256 is c459043e9fb30eb653541d3a0ebaddb10735512025ed57190c0cb12966dd89da. The raw dataset contains publisher news text inside `full_prompt`. The dataset and analysis are released in the public GitHub repository linked above. Public availability and a software license do not grant

redistribution rights to publisher text or other third-party content. The Overleaf project provides the editable report source. The original GPF manuscript is not changed by this new report.

A Complete 28-column dictionary

Column order matches the CSV exactly. Blank strings denote unavailable or unrecorded metadata. No columns are added to or removed from the supplied selected-column release. Analysis-derived developer labels and cleaned counts reside in separate files.

Column	Type and definition
run_id	string. Recorded generation/run identifier. It is inherited across some AUC and Gemini records and is not a globally unique row key. Retained for provenance, not used alone to join observations.
cell_id	string. Frozen experimental condition identifier encoding the article, Y label, and prompt family. The same condition appears for every model. The validated row key is (model_name, cell_id).
experiment_stage	categorical string. Recorded collection stage: primary or external_platform_extension. This is provenance rather than an independent experimental treatment; extension describes the Grok stream.
repeat	integer. Requested generation replicate index. Every supplied row has repeat=1, so within-condition generation variance cannot be estimated.
model_name	categorical string. Human-facing model label recorded during collection; twelve labels, 588 rows each. UI labels and latest aliases do not independently verify hidden serving checkpoints.
model_id	string. Recorded routing or model identifier. It may be a mutable latest alias, a UI alias, or unknown. Do not interpret it as a pinned model-weight revision.
model_provider	categorical string. Recorded serving provider or route. Values include together_ai and openrouter for Meta-family models; this column does not consistently identify the model developer. Analysis derives company from model family separately.
prompt_family	categorical string. One of seven question objectives: significance, impact, emotion, worldview, community, bias_check, or policy_action. Used as a controlled comparison stratum.
prompt_question	string. Identity-conditioned question, including the exact I am Y wording. The wording can itself elicit prescriptions or assumptions, especially in emotion and worldview questions.
full_prompt	multiline string. Exact frozen user prompt, including instructions, identity-conditioned question, source metadata, URL, and supplied article text. All twelve rows for a cell have the same string. Contains publisher-owned news content; handle as a private research artifact.
x_group_id	categorical string. Article identifier: bbc_brewdog or reuters_denmark. X is the source-news condition, not a participant group.
x_group_name	string. Article title captured for the X condition. Titles describe the articles used; they are not model outputs.
news_source	categorical string. Source label: BBC News or Reuters via Internazionale. Only one article per source is present, so source, article, topic, and supplied length are confounded.
news_source_link	URL string. Recorded source page URL. A provenance reference, not a guarantee that the page remains unchanged or accessible. Responses were requested to use supplied text without browsing.
news_author	string. Byline captured from source metadata: Paul Hastie for BBC and Stine Jacobsen for the Reuters item.
news_published_utc	date/time string. Publication metadata preserved as collected. BBC has a UTC timestamp; Reuters has only 2026-09-18, so exact time of day is unavailable. Do not silently impute a time.
news_modified_utc	nullable date/time string. Source modification timestamp when available. Blank for all 3,528 Reuters rows; blank means unknown rather than unchanged.

Column	Type and definition
news_retrieved_utc	date/time string. Recorded UTC article retrieval time. Shared across all responses to an article; not the response capture time.
news_word_count	integer. Recorded article-body word count: BBC 571 and Reuters 204. It does not count the entire prompt or model response.
y_group_dimension	categorical string. Design partition for the identity phrase: gender_sexuality, geography, political, race_ethnicity, religion, or socioeconomic. These inherited categories mix overlapping constructs and are not a validated demographic taxonomy.
y_group_id	string. Stable design label combining dimension and identity name. Used for matching and clustered uncertainty; it does not identify a person.
y_group_name	categorical string. Exact synthetic self-description inserted into the prompt. There are 42 labels with 14 prompts and 168 responses per label. These are experimental text perturbations, not sampled communities or measured attributes.
response	multiline string. Captured response text. The release preserves text verbatim, including some UI headings or citation-like fragments. Analysis removes only known leading UI wrappers and normalizes whitespace. Content anomalies remain flagged, not silently repaired.
response_word_count	integer. Stored collection-time word count. It can differ from the analysis recount after removal of UI wrappers and standardized whitespace splitting. Recomputed counts are provided in results/word_count_audit.csv.
captured_utc	date/time string. Recorded UTC capture timestamp, spanning September 19-27, 2026. This is collection provenance and may not be exact generation-start time or an independently audited server timestamp.
requested_word_range	string. Prompt length instruction, 100-150 words. This is a requested range, not an inclusion filter; long and short responses are retained.
length_status	categorical string. Stored within/outside-range label derived during dataset construction. Analysis reports its own consistently recounted length compliance and a both-responses-compliant sensitivity analysis.
thread_deleted	nullable boolean string. Historical collection flag, true or false for Gemini and blank for other streams. It is not independent verification of deletion, retention, or temporary-chat state; blank means unrecorded. No account-security conclusion follows from this field.

B All 42 Y labels and their measured roles

Every label has 14 prompts per model and 168 raw responses overall. All values below are MPNet means. Between-model distance matches the exact prompt across 66 model pairs. Within-model distinctiveness compares the label to the other labels in its dimension, holding model, article, and question family fixed, then averages over all twelve models. Screened distinctiveness omits the five flagged complete cells and can have unequal block/pair counts. These values describe relative textual behavior, not the importance of people.

Dimension	Y label	Matched model tance	Y distinctive- dis- ness	Screened Y dis- tinctiveness
gender_sexuality	Bisexual	0.112	0.178	0.178
gender_sexuality	Gay Male	0.119	0.159	0.158
gender_sexuality	LGBTQ+	0.107	0.164	0.163
gender_sexuality	Lesbian	0.127	0.171	0.171
gender_sexuality	Nonbinary	0.138	0.178	0.174

Dimension	Y label	Matched model tance	Y distinctive- dis- ness	Screened Y dis- tinctiveness

socioeconomic	Upper middle class	0.164	0.207	0.207
socioeconomic	Veteran	0.156	0.290	0.290
socioeconomic	Working poor	0.159	0.240	0.240

The complete 12-model-by-42-label matrix is available in `results/y_importance.csv` and its screened counterpart. Per-Y matched-model comparisons, including all 66 pairings for each label, are in `results/pairwise_by_y.csv`. This separation allows each label to be inspected without conflating within-model identity changes with between-model disagreement.

B.1 Per-model Y distinctiveness for every label

Column abbreviations follow this order: GPT = GPT 5.4; Mini = GPT 5.4 Mini; Son. = Claude Sonnet 4.5; Hai. = Claude Haiku 4.5; L3.3 = Meta Llama 3.3 Turbo; L4 = Meta Llama Maverick 4; G2F = Gemini 2.5 Flash; G2P = Gemini 2.5 Pro; ML3 = Mistral Large 3; MM3 = Mistral Medium 3; Grok = Grok Fast; G3L = 3.5 Flash-Lite. All entries are full-data MPNet distances to other labels within the same dimension, averaged over fourteen article-family blocks. Full raw and screened values are also available in machine-readable files.

Y label	GPT	Mini	Son.	Hai.	L3.3	L4	G2F	G2P	ML3	MM3	Grok	G3L

C All 66 matched model-pair results

Full-data MPNet means use 588 prompts; screened means use 583 prompts. Intervals are identity-cluster percentile bootstrap intervals conditional on the two fixed articles. These are descriptive comparisons without significance-based ranking claims.

Model A / Model B	Full mean	95% interval	Screened mean
